42.10.49.76Comparison of two methods for recording intradermal allergy testing. Intradermal testing with various allergens is considered as one of the most valuable methods in diagnosing cutaneous allergy. The histamine-provocative test (HPT) and the autologous serum skin test (ASST) are two commonly used methods in this diagnostic procedure. As these two tests are currently used for diagnosing cutaneous allergy in various laboratories, the aim of this study was to compare the sensitivity and specificity of these two methods for diagnosing cutaneous allergy. In a prospective study, 38 patients were tested with the two methods. Positive results were established by skin testing and/or RAST. HPT was performed as a one-step method with 4 microl of 1:100 diluted histamine. As the standard, ASST was performed by injecting 0.1 ml of patient's own serum into the intradermal testing site. The sensitivity of the HPT was 84% and specificity was 75%. When the ASST was compared with the HPT, the sensitivity was 94% and the specificity was 91%. In patients with a positive RAST, the sensitivity of the HPT was 72% and specificity was 83% in the group with negative RAST. The sensitivity of the ASST in this group was 81% and specificity was 91%. In contrast, the sensitivity of the HPT was 97% and specificity was 78% in the group with negative RAST and with a positive skin test. The method of testing, i.e. HPT or ASST, used for diagnosing cutaneous allergy must be chosen for a particular case. The sensitivity of the HPT is considerably lower in comparison with the ASST in patients with a negative RAST, and a negative skin test. In patients with a positive RAST and negative skin test, the specificity of the HPT is higher. In patients with a positive RAST and a negative skin test, the sensitivity of the ASST is higher. As the specificity of the ASST is lower than that of the HPT, it is a method of choice for diagnosing cutaneous allergy in this group.TODAY: Of course, when the Yankees announced the deal, the presence of Masahiro Tanaka and Alex Rodriguez under a cloud became clear. Tanaka has spent time on extended leave, and A-Rod, who will not be the DH in this deal, won't be joining the team for the rest of the season 82157476af
